Optimizing Biologic Therapy in Rheumatic Disease

*DoseASSURE™, Labcorp’s portfolio of biologics monitoring assays, may help physicians optimize biological therapy using a personalized, patient-specific approach by:

- Aiding in titrating doses and adjusting frequency to maximize effectiveness
- Identifying lack of response due to non-compliance or under-treatment
- Assisting in preventing and managing loss of response due to immunogenicity
- Predicting which patients are likely to retain long-term response
- Minimizing cost to patient by avoiding unhelpful dose escalation
- Avoiding overtreatment in low disease activity cases where tapering down is desirable
- Elucidating poor response as due to undertreatment (pharmacokinetic), mechanistic mismatch (pharmacodynamic) or development of anti-drug antibodies

DoseASSURE test portfolio provides tests for both drug concentration (TDM) & anti-drug antibody (immunogenicity)

### Therapeutic Drug Monitoring (TDM)

- Biologics have variable pharmacokinetics.
- Dosing by weight and empiric dose adjustment may be inefficient and suboptimal.
- Clinical efficacy in RA and/or psoriasis has been shown to correspond with serum concentrations of infliximab, adalimumab, etanercept, golimumab, rituximab, and ustekinumab.
- TDM for biologics is a valuable tool to evaluate doses and to tailor dose adjustments to your individual patient.
- TDM can help differentiate non-compliance and under-treatment from other causes of lack of response.
- Personalized treatment using TDM has been shown to improve both clinical and cost-effectiveness in RA.

### Immunogenicity Testing (Anti-drug Antibody level)

- All biologics have the potential to induce an antibody-mediated immune response.
- As many as one third of RA patients on biological therapy may develop anti-drug antibodies.
- Anti-drug antibodies may appear as early as 2 weeks or as late as 3 years after the first infusion.
- Co-therapy with methotrexate, sufficient drug levels, and maintenance dosing (vs. episodic or on-demand use) reduce the risk of anti-drug antibody formation.
- Anti-drug antibodies can adversely affect the amount of drug in the body. Therefore, concomitant measurement of anti-drug antibodies is an important adjunct to TDM for biologics.

Interpreting Drug Concentrations

- Higher drug trough levels have been correlated with clinical improvement as well as to higher rates of response and remission in rheumatic diseases.4-13
- A consensus has yet to be reached about target ranges and maximally effective concentrations.1

Optimal drug concentration depends on the disease and the desired therapeutic endpoint.

</table>

§Note: These targets ranges were those used in landmark studies and do not necessarily translate into general recommendations for individual patients.

Interpreting Anti-Drug Antibody Levels

- Anti-drug antibodies may impact pharmacokinetics, efficacy, and cost-effectiveness.
- Low titer antibodies may have little or no effect on drug levels or clinical outcome. In fact, they may be transient and disappear over time, or they may progress to increasing titers.1,6,18,21
- In contrast, high titers of antibodies are likely to be more consequential, leading to loss of drug efficacy by preventing drug binding to TNF and/or increasing drug clearance.1,6,19

Anti-drug antibody positivity should be interpreted in the context of the concomitant free drug level.

When & where to collect blood on my patients?

- The timing of sample collection is important because the drug concentration will change during the dosing interval.
- The Trough Concentration (TC) is measured at the least variable time in the dosing interval, just before the next dose (same day to within ~7 days depending on the drug’s normal half-life).
- During induction and maintenance phases, trough collections are usually recommended because target ranges are defined using TC.
- Blood can be drawn at any of Labcorp’s nearly 2000 patient service centers located nationwide.
